## Data Stage of the ML Production Lifecycle

Latest Submission Grade 100%

	Which of these statements do you agree with regarding structured vs. unstructured data problems?	1 / 1 point
	<ul> <li>It is generally easier for humans to label data and to apply data augmentation on unstructured data than structured data.</li> </ul>	
	It is generally easier for humans to label data on unstructured data, and easier to apply data augmentation on structured data.	
	It is generally easier for humans to label data on structured data, and easier to apply data augmentation on unstructured data.	
	It is generally easier for humans to label data and to apply data augmentation on structured data than unstructured data.	
	Correct That's right! Humans are better able to label unstructured data such as images and audio clips than complex, high-dimensional structured data. As well, it's not always possible to apply data augmentation to structured data.	
:.	Take speech recognition. Some labelers transcribe with "" (as in, "Um today's weather") whereas others do so with commas ",". Human-level performance (HLP) is measured according to how well one transcriber agrees with another. You work with the team and get everyone to consistently use commas ",". What effect will this have on HLP?	1/1 point
	HLP will stay the same.	
	HLP will increase.      HLP will decrease.	
	<ul> <li>Correct         That's right! Since the labels will be more consistent, the labelers will agree with each other more often, raising HLP.     </li> </ul>	
	Take a phone visual inspection problem. Suppose even a human inspector looking at an image cannot tell if there is a scratch. If however the same inspector were to look at the phone directly (rather than an image of the phone) then they can clearly tell if there is a scratch. Vor goal is to build a system that gives accurate inspection decisions for the factory (not publish a paper). What would you do?  Get a big dataset of many training examples, since this is a challenging problem that will require a big dataset	1/1 point
	to do well on.  Try to improve the consistency of the labels, y.	
	Try to improve their imaging (camera/lighting) system to improve the quality or clarity of the input images x.	
	Oracfully measure HLP on this problem (which will be low) to make sure the algorithm can match HLP.	
	Correct That's right! If even a human looking at the image cannot identify the presence of a scratch, you'll need to improve the optical quality of your camera to improve your system's performance.	
١.	You are building a system to detect cats. You ask labelers to please "use bounding boxes to indicate the position of cats." Different labelers label as follows:	1/1 point

- O That this should have been posed as a segmentation rather than a detection task.
- Ambiguous labeling instructions.
- Lazy labelers.
- O Labelers have not had enough coffee.

Ocrrect
That's right! Your hardworking labelers may interpret the ambiguous instructions differently and label the

5. You are building a visual inspection system. HLP is measured according to how well one inspector agrees with another. Error analysis finds:

1/1 point

(ii) makes predictions. An engineering team improves the system used for step (i). If the trained model for step (ii) remains the same, what can we confidently conclude about the performance of the overall system?  It will definitely improve since the data is now more clean.  It will get worse because changing an earlier stage in a data pipeline always results in worse performance of the later stages.  It is not possible to say - it may perform better or worse.  It will get worse because stage (ii) is now experiencing data/concept drift.  Correct That's right! It's really hard to tell, as it depends on how the data was changed, and how your model behaves.  What is the primary goal of building a PoC (proof of concept) system?  To collect sufficient data to build a robusts system for deployment.  To select the most appropriate ML architecture for a task.  To build a robust deployment system.  To check feasibility and help decide if an application is workable and worth deploying.  Correct That's right! A proof of concept system is a simple way to determine whether its worth the time and effort to develop the product.						
It will get worse disciplinate and search of the search of		-				
it is more promising to check damp covertably improve) blade consistency on discoloration defects than scratch defects, since HLP is lower on discoloration and thus there's more room for improvement.  It is more promising to check damp commandly improved blade consistency on scratch defects than scratch defects, since HLP is leyther on scratch defects and thus it's more reasonable to expect high consistency.  It is more promising to check damp commandly improved blade consistency on scratch defects than scratch defects, since HLP is leyther on scratch defects and thus it's more reasonable to expect high consistency.  Cornect Thurs right HLP is layther for discoloration defects, perhaps there is an opportunity to improve this metric by improving label consistency.  To implement the data iteration loop effectively, the key is to take all the time that's needed to construct the right disasser first, so that all development can be done on that dataset without needing to spend time to update the data.  False  Or cornect All the defects are all development can be done on that dataset without needing to spend time to update the data.  True  Cornect All places predictions. An engineering team improves the system used for step (ii) fine trained model for step (ii) remains the same, what can we confidently conclude about the performance of the overall system?  It will definitely improve since the data is now more dean.  It will get worse because changing an earlier stage in a data pipeline always results in worse performance of the later stages.  It will definitely improve since the data is now more dean.  It will get worse because changing an earlier stage in a data pipeline always results in worse performance of the later stages.
